Research first: 113 linked notes behind every design decision.

Research, 9 notes Concepts, 45 Decisions, 39 Features, 15

1. **Read the rules and the evidence.** FCA complaint deadlines, AI threats and controls, verification and automation bias, UX evidence, how bank complaint teams work today.
2. **Check every fact at its source.** Anything not opened is marked unverified and kept off the screens.
3. **One note per decision:** who made it, the evidence, the trade-off and what would change it. An Obsidian vault in the repo.
4. **Spec, then a 13-task plan,** then build test-first, each task checked by a separate reviewer.
5. **Scope kept small:** one bank, one journey, synthetic data only.

ankura

Handlers spend their time on judgement, not on reading and retyping.

1.85 million

complaints reached UK firms in the first half of 2026, each on an 8-week clock (FCA).

90.5%

routed to the right team when the model is sure; the 11.3% it is unsure of go to a person.

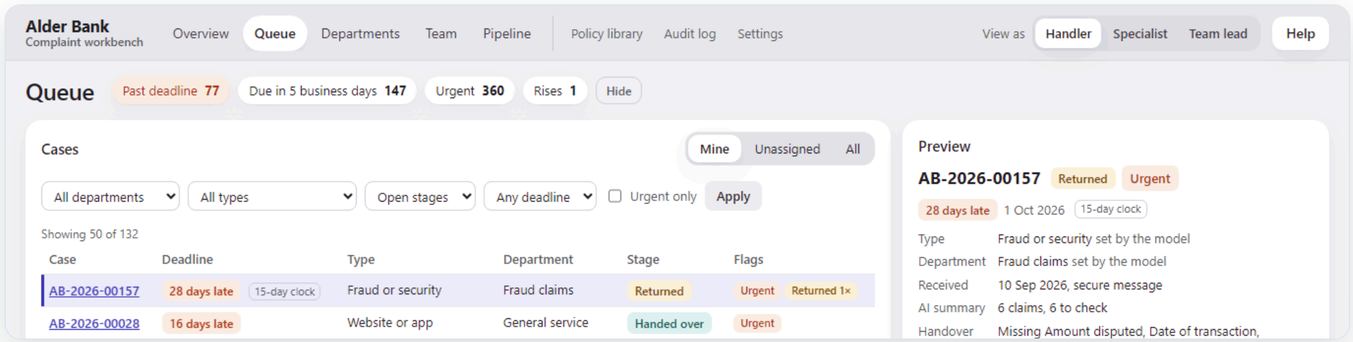

8 clicks

from the queue to an approved, checked handover on the demo case.

One window

every deadline, what falls due next and what needs this person.

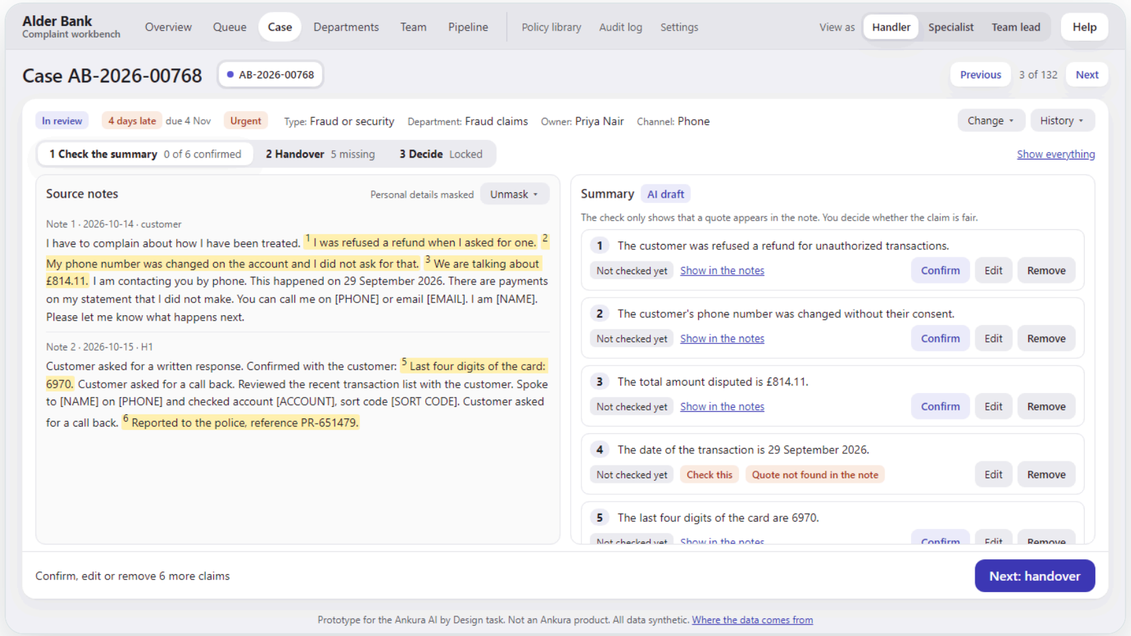

ROLE	TODAY	WITH THE WORKBENCH
Handler	Reads every note, retypes the handover	Checks an AI summary claim by claim against its quotes
Specialist	Finds gaps, sends cases back	Sees missing fields before accepting; a return needs a reason
Team lead	Chases deadlines case by case	Sees the flow, the rises and the load; no speed league table
New skill	Writing summaries	Judging AI output: each claim confirmed, never bulk-approved

Value is time per case and fewer handovers sent back; neither is measured on real work yet. "Today" is our description, not a measurement.

The model drafts. A person decides, claim by claim.

RISK	CONTROL	MEASURED
Invented or wrong claim	Each claim needs a word-for-word quote; a person confirms each one	**42 of 864 blocked**
Personal data reaches the model	Masked first; unmasking needs a reason and is logged	**21 of 22 caught**
Sent to the wrong team	Unsure cases wait for a person	**11.3% to a person**
Hidden instructions in a complaint	Notes are fenced as data; output checked	**0 of 1 changed**
Silent edits afterwards	Hash-chained audit of every action	**Detected, not prevented**

Also: urgent reasons shown in words, no bulk approve, nothing leaves the machine (no network calls, strict content policy).

ankura

Clear about the limits, and about the AI that built it.

Assumptions

All data is synthetic, shaped by public FCA, ombudsman and UK Finance figures. Channel mix and time of day are our guesses; Settings lists each source.

Limits

A quote check proves the words exist, not that the summary is fair. Policy search finds the right clause 13 times in 20. The role switch is a demo, not a login.

Trade-offs

A small local model with drafts recorded in advance: private and repeatable, not live. Classic models for routing: cheap and explainable.

AI in the product

`TF-IDF + logistic regression` routing `BM25` policy search

`qwen3:4b-instruct` drafts, run locally. One stage in ten uses a language model.

AI in the build

`Claude Code` a controller ran builder and reviewer agents, four builders in parallel at the peak

`Codex` the case flow diagram `Local Qwen` the recorded drafts

Assessment

`Worked` separate reviewers caught masking leaks, an audit gap and an accuracy figure that flattered itself (0.894 fell to 0.844).

`Did not` an agent read "too busy" as "too many charts"; the owner corrected it. Codex could not commit from its sandbox.

Full figures and misses: docs/test-results.md. Build log: docs/loop-log.md.

ankura

Built and tested like a product, not a demo.

Citation check

Every AI claim must quote the notes word for word. **42 of 864** were blocked.

Mask before the model

Names, cards and accounts masked first; unmasking needs a reason, and it is logged.

Tamper-evident audit

Every action hash-chained; the log checks itself and flags any edit.

One window, any role

9 pages, 3 roles, 2 screen sizes: **63 browser checks** that nothing runs off the screen.

No build, no network

Server-drawn charts, a strict content policy, no outside calls while in use.

Multi-agent build loop

A ledger, parallel builders, read-only reviewers, Codex and a local model, each on the cheapest tier that could do the job.

DATA HANDLED

1,600 cases: every page under 100 ms. At 16,000 the Overview takes 345 ms: a known limit

SECURITY

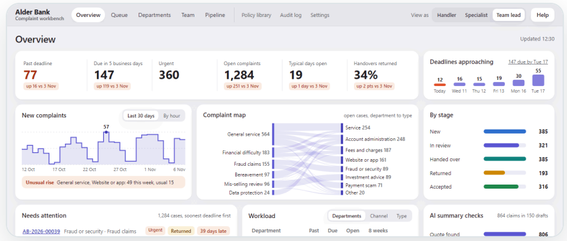

Injection, tamper, cross-site and host checks pass; masking 21 of 22

EASE OF USE

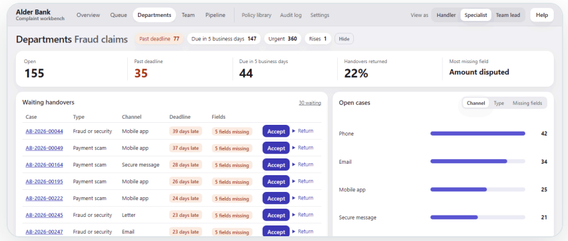

8 clicks queue to approved; keyboard reachable; one window

TESTS

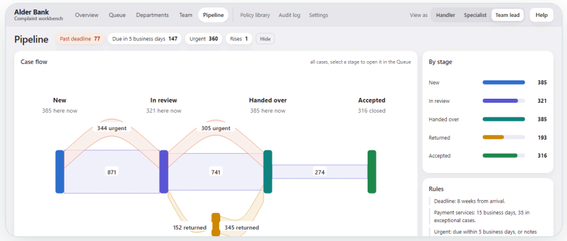

527 automated tests, 424 unit and 103 browser, all passing
